PROVISIONAL SPECIFICATION.

Improvements in or relating to Electric Protective Arrangements.

We, A. REYROLLE & COMPANY LIMITED, a company registered under the laws of Great Britain, of Hebburn-on-Tyne, County of Durham, and BRUCE HAMER LEESON, British subject, of "Waverley", Tynemouth, County of Northumberland, do hereby declare the nature of this invention to be as follows:—

This invention relates to electric protective arrangements and has particular reference to the protection of parallel feeders, either in the form of cables or overhead lines, arranged on what is known as the split conductor system. An example of such a system would be a three-phase supply or distribution system in which each phase conductor is split, i.e. formed of two similar conductors, one of the parallel feeders consisting of three of such conductors and another parallel feeder of the other three.

It is known to protect such an arrangement by providing each pair of split conductors with a transformer whose secondary winding is energised when there is want of balance in the currents in the two split conductors due to a fault in one of them, the resulting current in the secondary winding operating through a relay to cut out both feeders. This known arrangement automatically discriminates between the two feeders and the rest of the system but if as is usually the case only one of the feeders is faulty and it be desired to put the sound feeder again into commission, tests are necessary and loss of time is involved.

The object of the present invention is to provide for such a case and its object is accomplished by so constructing and connecting the relay that it not only trips the two feeders out but also acts as an indicator to show which feeder is faulty. Thus without any test the faulty feeder can be cut out of the system by opening

isolating switches and the remaining sound feeder replaced in commission where it preferably then works under overload protection.

This indicating or directional action of the relay is brought about by providing it with a potential or polarising coil energised for instance from the secondary winding of a potential transformer on the supply mains. The other coil of the relay is in series with the secondary winding of the split conductor transformer in the usual way.

The polarising coil is preferably wound upon an armature or other part of the relay which may be pivoted or otherwise mounted in movable relationship to the other portions of the relay. The relay is provided with two sets of tripping circuit contacts so that movement in either direction will trip out the feeders. The direction of movement will, however, depend upon the direction of flux in the core of the split conductor transformer which naturally is determined by which of the conductors is sound and which faulty.

The indication given by the relay may be of any convenient nature visible or audible.

Preferably the circuit connecting the relay with the secondary winding of the transformer is provided with a switch so arranged that as soon as the two feeders have been tripped out and the faulty feeder isolated, the sound feeder may be placed under overload protection. This switch may be of simple form arranged to break the connection to the indicating and tripping relay and make connection to an overload relay.

As an example of the application of the invention the following is given:— The supply mains of a three-phase system are split say at an oil switch and each pair of split phase conductors is

THIS PAGE BLANK (USPTO)

taken through the core of a current transformer, one of such split phase conductors then passing through an isolating switch to one feeder and the other
5 through another isolating switch to another feeder.

The secondary coil of each split conductor transformer is then connected through a switch to the operating
10 coil of a relay which is made directional in its action by providing it with a polarising coil energised from the secondary of the potential transformer. In this example one three-phase potential
15 transformer might be employed having its primary coils connected to each of the supply phase conductors before they are split at the oil switch. These primary coils may be star-connected and the
20 secondary coils also star-connected might

be connected respectively to the polarising coils of the relays. Each relay would have two sets of contacts appropriately connected to a common tripping circuit supplying current directly or indirectly to
25 a trip coil on the main oil switch.

If it be desired to render the operations subsequent to the tripping out of the two feeders automatic this may be done by providing circuits and electro-
30 magnetic devices controlled by the relays which will act to open the isolating switches of the faulty feeder, place the overload relay in operative connection with the sound feeder and close the main
35 oil switch.

COMPLETE SPECIFICATION.

Improvements in or relating to Electric Protective Arrangements.

40 We, A. REYROLLE & COMPANY LIMITED, a company registered under the laws of Great Britain, of Hebburn-on-Tyne, County of Durham, and BRUCE HAMER
45 LEESE, British subject, of "Waverley", Tynemouth, County of Northumberland, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the
50 following statement:—

This invention relates to electric protective arrangements and has particular reference to the protection of parallel feeders, either in the form of cables or
55 overhead lines, arranged on what is known as the split conductor system. An example of such a system would be a three-phase supply or distribution system in which each phase conductor is split, i.e. formed of two similar conductors, one
60 of the parallel feeders consisting of three of such conductors and another parallel feeder of the other three.

It is known to protect such an arrangement by providing each pair of split conductors with a transformer whose secondary winding is energised when there is want of balance in the currents in the two split conductors due to a fault
70 in one of them, the resulting current in the secondary winding operating through a relay to cut out both feeders. This known arrangement automatically discriminates between the two feeders and the rest of the system but if
75 as is usually the case only one of the feeders is faulty and it be desired to put

the sound feeder again into commission, tests are necessary and loss of time is involved.

The object of the present invention is to provide for such a case and its object is accomplished by so constructing and connecting the relay that it not only trips the two feeders out but also acts as an indicator to show which feeder is faulty. Thus without any test the faulty feeder can be cut out of the system by opening isolating switches and the remaining
90 sound feeder replaced in commission where it preferably then works under overload protection.

This indicating or directional action of the relay is brought about by providing it with a potential or polarising coil energised for instance from the secondary winding of a potential transformer on the supply mains. The other coil of the relay is in series with the secondary winding of the split conductor transformer in
100 the usual way.

The polarising coil is preferably wound upon an armature or other part of the relay which may be pivoted or otherwise mounted in movable relationship to the
105 other portions of the relay. The relay is provided with two sets of tripping circuit contacts so that movement in either direction will trip out the feeders. The direction of movement will, however, depend upon the direction of flux in the core of the split conductor transformer which naturally is determined by which of the conductors is sound and which
115 faulty.

The indication given by the relay may be of any convenient nature visible or audible.

Preferably the circuit connecting the relay with the secondary winding of the transformer is provided with a switch so arranged that as soon as the two feeders have been tripped out and the faulty feeder isolated, the sound feeder may be placed under overload protection. This switch may be of simple form arranged to break the connection to the indicating and tripping relay and make connection to an overload relay.

As an example of the application of the invention the following is given:— The supply mains of a three-phase system are split say at an oil switch and each pair of split phase conductors is taken through the core of a current transformer, one of such split phase conductors then passing through an isolating switch to one feeder and the other through another isolating switch to another feeder.

The secondary coil of each split conductor transformer is then connected through a switch to the operating coil of a relay which is made directional in its action by providing it with a polarising coil energised from the secondary of the potential transformer. In this example one three-phase potential transformer might be employed having its primary coils connected to each of the supply phase conductors before they are split at the oil switch. These primary coils may be star-connected and the secondary coils also star-connected might be connected respectively to the polarising coils of the relays. Each relay would have two sets of contacts appropriately connected to a common tripping circuit supplying current directly or indirectly to a trip coil on the main oil switch.

If it be desired to render the operations subsequent to the tripping out of the two feeders automatic this may be done by providing circuits and electromagnetic devices controlled by the relays which will act to open the isolating switches of the faulty feeder, place the overload relay in operative connection with the sound feeder and close the main oil switch.

The accompanying drawings is a diagram illustrating a protective arrangement according to this invention.

In this diagram A, B and C represent split conductors or bus-bars each divided at an oil-break switch D into two conductors A¹, A²; B¹, B²; and C¹, C² respectively. Each pair of split conductors is furnished with a transformer represented by the cores E, E¹ and E² and after passing

through the core one member of each split conductor is taken to an isolating switch F and the other member to another isolating switch F¹ so that there are two parallel feeders, one comprising the conductors A¹, B¹ and C¹ and the other the conductors A², B² and C².

Each of the split conductor transformers E, E¹ and E² has a secondary winding but for the sake of clearness only one is shown at G. This secondary winding is joined through a switch H to the operating coil J¹ of a relay J having a pivoted armature J² wound with a polarising coil J³. This polarising coil J³ is energised from the secondary winding K¹ of a potential transformer whose star-connected primary windings K are joined to the split conductors A, B and C.

The armature J² of the relay J bears two contacts J⁴ and J⁵ controlling respectively gaps L and L¹ in circuits containing indicators or signalling devices M and M¹. Each of these circuits forms part of a circuit end which includes a relay or electromagnet O controlling the main switch D.

Under normal conditions no current will flow through the secondary winding G of the split conductor transformer E² but if a fault occurs either on the conductor C¹ or C² a current will flow and will energise the operating coil J¹ of the relay. As the armature of that relay is polarised it will move one way if the fault occurs in C¹ and the other way if the fault is in C². In either case the circuit containing the main switch coil O is closed and the switch D opened. At the same time an indication is given at M or M¹ as to which feeder is faulty and consequently the appropriate isolating switch F or F¹ can be opened by hand to cut the faulty feeder and the main switch may then be closed to put the sound feeder again into commission. Before doing this the switch H is moved into the dotted position thus cutting out the relay J and connecting the secondary winding G to some suitable overload protective device diagrammatically indicated at P.

It will be understood that the secondary windings of the other two split conductor transformers E and E¹ would be connected to relays similar to that described, that the armatures of those relays would be polarised from coils similar to the coil K¹ and that the operation of any one of the three relays would have the effect of energising the coil O, opening the main switch D and giving an indication as to which feeder was faulty.

Having now particularly described and ascertained the nature of our said inven-

tion and in what manner the same is to be performed, we declare that what we claim is:—

- 5 1. A protective arrangement for a parallel feeder split conductor system in which the relay which trips out the parallel feeders is so constructed as to give an indication as to which feeder is faulty.
- 10 2. A protective arrangement for a parallel feeder split conductor system as claimed in Claim 1 in which the relay is provided with a polarising or potential coil energised from the supply mains and

acting in conjunction with a split conductor to give a directional movement of the moving member of the relay dependent on the direction of the magnetic field of the split conductor.

3. The protective arrangement for a parallel feeder split conductor system substantially as described in the accompanying drawings.
